# Chapter 1

## Introduction

### 1.1 Abstract

### 1.2 List of Terms

# Chapter 2

## Overview

### 2.1 Features

### 2.2 Roles

### 2.3 Usecases

### 2.4 Architecture

### 2.5 Components

### 2.6 Dependencies

#### 2.6.1 Depending on following standards:

- JSON Object Signing and Encryption

#### 2.6.2 Depending on following technologies

# Chapter 3

## Data

- What data the user should be able to manage or to control?
- request should contain a specific value for how precise a certain data should be (e.g. location)
- differentiate between data the user has and collects about herself, and data others have/create on the user (e.g. doctors/e-health, banks, public authorities) - depending on that, how does the data get into the system?
- data precision/resolution? (maybe it might be legit to say: the more precise the data is, the higher the (selling) value)
- when responding with data, the contents should be labeled with an expire date, set by the owner of the data
- NOTE, in reality, certain business processes might require to store some data, e.g. for legal a/o administrative reasons - address to reproduce where amazons package went

## 3.1 Data Categories

**NOTE:** does not mean data types!

- profile data
- sensor data (e.g. geo-location, motions)
- financial record (and history)
- payment information
- medical record
- governmental data
- biometric datasets (e.g. finger print, retina)
- web search history
- what about user-created content, like pictures, videos or blog posts?

[A-middleware-architecture-for-privacy-protection\_2007 p4r] suggests:

- active
- semi-active
- passive

## 3.2 Data types

- String (number, boolean) - single values, which can go into the db
- serialized data structure (as string); requires schema upfront
- data series based on time (recurring data with familiar structure and purpose)
- files - text or binary - need to get written to a filesystem and referenced by link with a db entry OR gets stored directly into the db

## 3.3 Dev API

- devs can registering new data types by providing a type name, description and a schema
- querying data by using graphql would provide the ability to ask fine-granted and structured based on a schema-like way
- every schema needs a version; we need to store every schema version

# Chapter 4

## Concepts

### 4.0.1 remote computation (aka block-chain, MITs SafeAnswer)

- during execution, http requests could be allowed, if information, such as domain, protocol, request and response body, mime-type will be provided up front (like *Content Security Policy*)
- we might need some kind of formal assurance policy (aka contract) signed by both sides

# Chapter 5

## Architecture

What is this data service look like? Which parts and tasks does it cover?

- hard-connection backend and mobile device? (for continuously collection data e.g. geo-location) -> internal aggregation;  
or soft-connection between them -> just exposing api to store certain types of arbitrary data,  
collected and stored/cached on external sources
- automated backup mechanisms, e.g. distribute encrypted container, maybe on a regular basis,  
to dropbox (or the like) or git repository or maybe scp
- 2-factor auth? How?
- an inclusion of a mobile device (as the actual data vault/container) could make using  
2-factor-auth more obvious and easier to implement - we might get in for free depending on  
we model the interaction processes
- data backup?
- explicitly no ecosystem approach: no interoperability between each individuals PDS,  
thus no market/appstore as business model
- either cloud-based (not in the near of the user) and/or local (users device) storage

# Chapter 6

## API

# Chapter 7

## Interfaces

How third parties can interact with such data sources?

- when requesting time series data, which concepts should be supported:
  - A) collection data within the service and only after a period of time handing over the data (after filtering them)
  - B) providing some sort of real time feed through the service (filtering upfront)?
- after introducing the system and because it is likely that vendors will support this way of exchanging/acquiring data only if its feasible and enough user are already using it. So to increase adoption rate of users, it might be supportive to provide a browser extension to mimic the role of the vendor somehow (like *Personal* did before [<https://techcrunch.com/2011/11/17/personal-is-a-secure-vault-for-all-of-your-private-digital-data/>]); also it would be great to have some client-plugins for several platforms, languages and frameworks right from the start (e.g. nodejs, shopify, rails, wordpress etc.)
- spam protection? if we have a general URI (endpoint) for incoming requests, which had to get submitted upfront, that identifier (URI) might get known com-

monly, thus unintended mass  
requests might occur. possible solution: generate URI+token (token =  
cert fingerprint?)  
within the software? (how do we get it from there to the third-party?)  
OR let the user  
create a human readable slug on the fly during the external interaction  
- therefor on the  
mobile notification we have at least sth to validate, but with no tech.  
assistance, and  
it is still not spam-safe?

# Chapter 8

## Components

### 8.1 mobile app

- notification receiver
- permission manager
- admin panel
- data collector (geo-location, movement, health data, etc.)

### 8.2 statistics, monitoring, self-healthiness and logging

- logging request of external services (when, what, why)
- watching and detecting anomalies (e.g. cert changed, domain changed, etc.)

### 8.3 Core

- self-detection host system to measure how secure the env is, I am currently in

# Chapter 9

## Security

### 9.0.1 providing self-collected (meta) data

- when handing over large amount of meta data (e.g. geo location log over time), these data have to be anonymized before leaving the system (see: MITs *openPDS* project, more precisely *SafeAnswer*)
- there have to be a protocol for such a process (details on what data they exactly need)
- end-to-end encryption everywhere, or when its sufficient transport encryption only?

# Chapter 10

## Visualization

- what should the admin panel look like?
- How should the data be visualized - and where?

# Chapter 11

## Interactions

- what type of interaction patterns are available - and where?
